

(I)

① Unlike the Windows File system, where it uses DRIVE LETTERS, Linux stores everything within a single directory structure called a virtual directory.

WINDOWS

e.g. c:\ Users \ Rich \ Documents \ test.doc

indicates that test.doc is located in Documents, which itself is located in directory Rich,

Rich is contained in directory Users, which is located on the hard disk partition assigned letter C. } C ← usually the first Hard Drive on the PC }

LINUX

e.g. /home / rich / Documents / test.doc indicates only that the file test.doc is in directory Documents, under the directory rich, which is contained in the directory home.

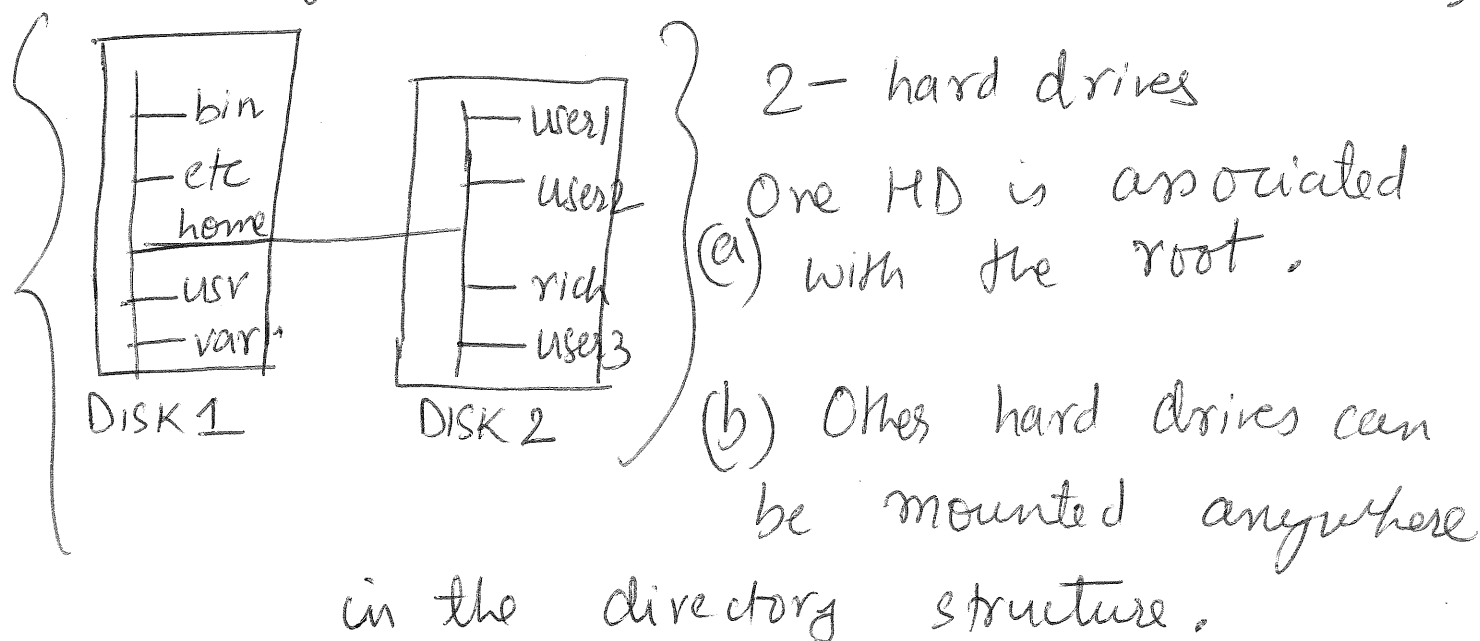

IT DOES NOT PROVIDE INFORMATION AS TO WHICH PHYSICAL DISK ON THE PC THE FILE IS STORED

HOW DOES LINUX INCORPORATE EACH STORAGE DEVICE?

1. FIRST HARD DRIVE INSTALLED IN A LINUX PC IS CALLED ROOT DRIVE.

root drive contains core of the virtual directory. Everything else builds from there.

2. On the ROOT DRIVE, Linux creates mount points (these are special directories where you assign additional storage devices)

2nd HD is mounted on /home, where user directories are located.

Linux

System

LS-F
Directories

Need to know about them in case your scripts need to refer to them

Directories created during installation of Linux

/

Root directory \leftarrow files stored here

core of the directory system

Binary utilities such as GNU user programs Firefox

Boot directory, GRUB, Linux Kernel

Boot loader

Device Files such as Sound card, etc.

Configuration files, Useful for programs to know how to behave

User directory

Library files used by the System

[Important for booting system]

temporary connected devices such as USB, Flash drives, CDROM

/sbin

/tmp

temporary files

System binary files used by executables the root only (e.g. clock, update, shutdown)

/var

Typically contain log files

Your home directory path is stored in Variable called \$HOME

/ \rightarrow Forward slash (Linux)

\ \rightarrow Back slash (Windows)

Change directory

cd / ← change to root directory
cd .. ← changes to parent directory
cd ../_ ← changes to sibling directory

CHANGE DIRECTORY

• ← Current directory
.. ← Parent directory
~ ← Home directory

cd ../../_ ← two levels up

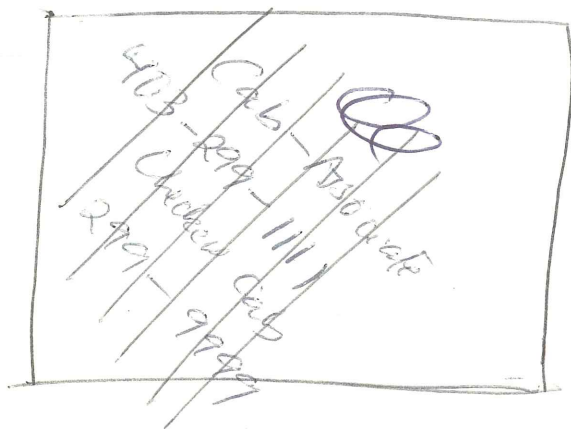

Directory commands.

Pwd and LS

pwd ← print working directory
tells you where you are

ls ← lists directory

{ Absolute path name
to my home directory }

/afs/ec.auckland.ac.nz/users/a/m/amah811/
unixhome

To refer to file 1 in my home directory,
the absolute path name;

⇔ /afs/ec.auckland.ac.nz/users/a/m/amah811/unixhome/
file1.txt

If my current directory is

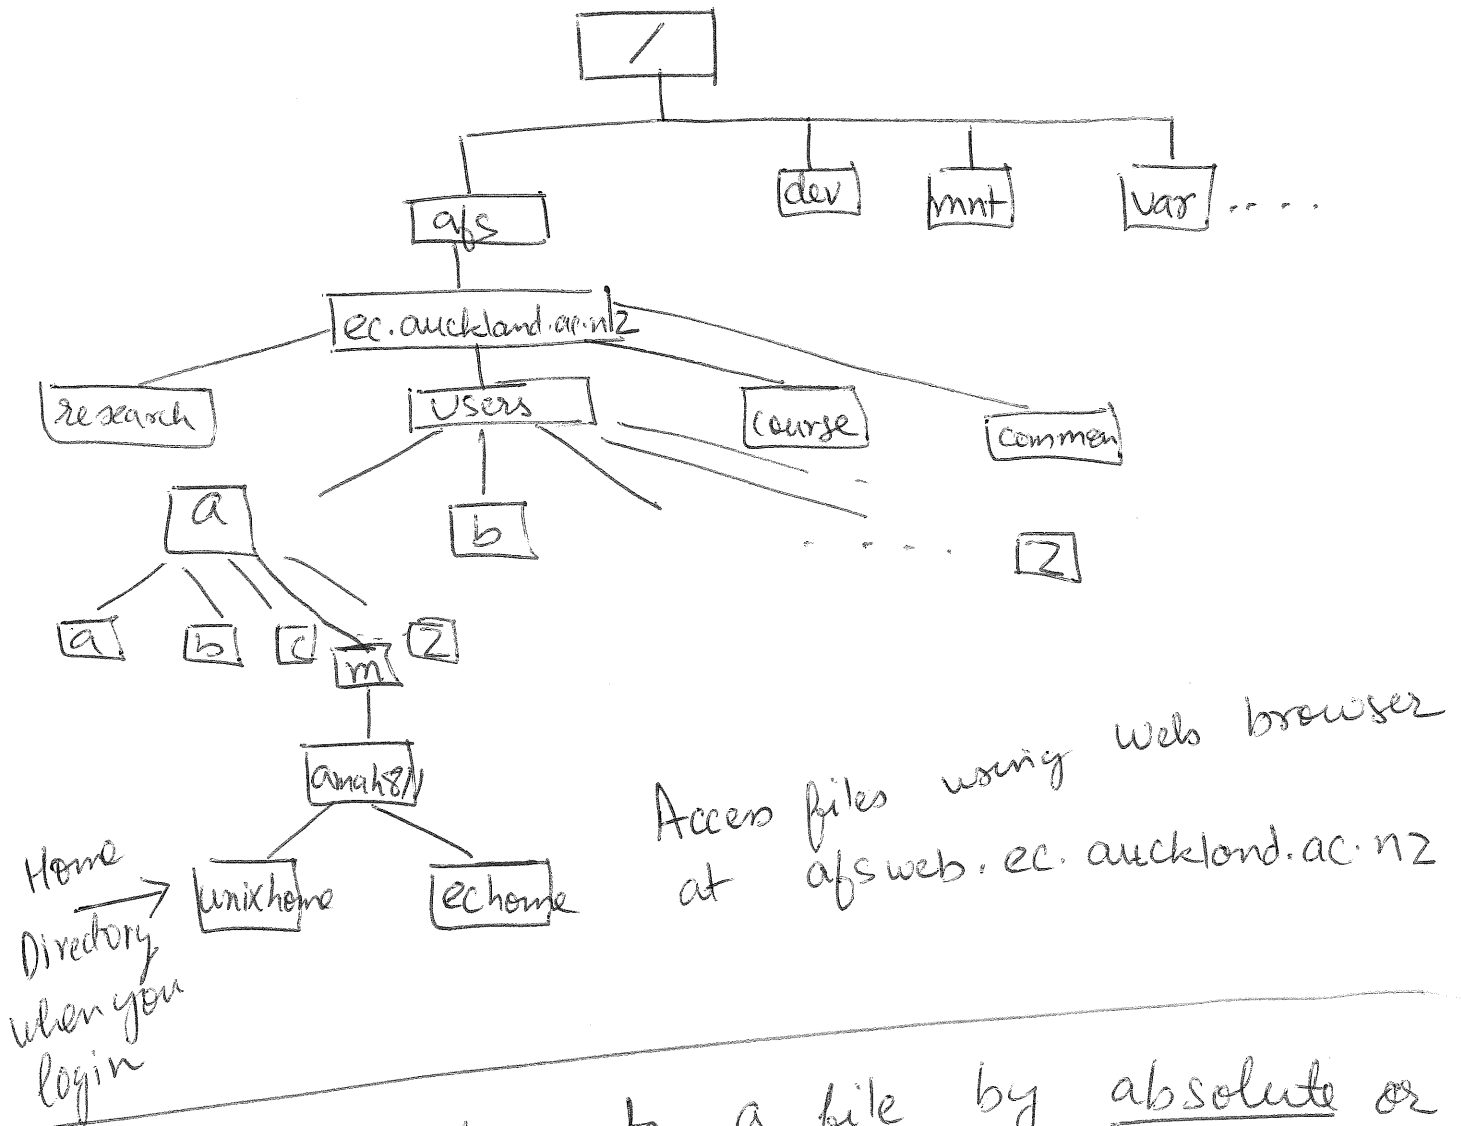

" /afs/ec.auckland.ac.nz/users/a/m/amah811 "

Relative path to file 1.txt in my home
directory is unixhome/file1.txt

and relative path to my home directory
is unixhome.

University Directory ~~File~~ Structure

— We can refer to a file by absolute or relative path names.

- ① Absolute path name: Specifies full path from the root to the desired directory or file.
- ② Relative path name: Path from current directory to a file or directory.

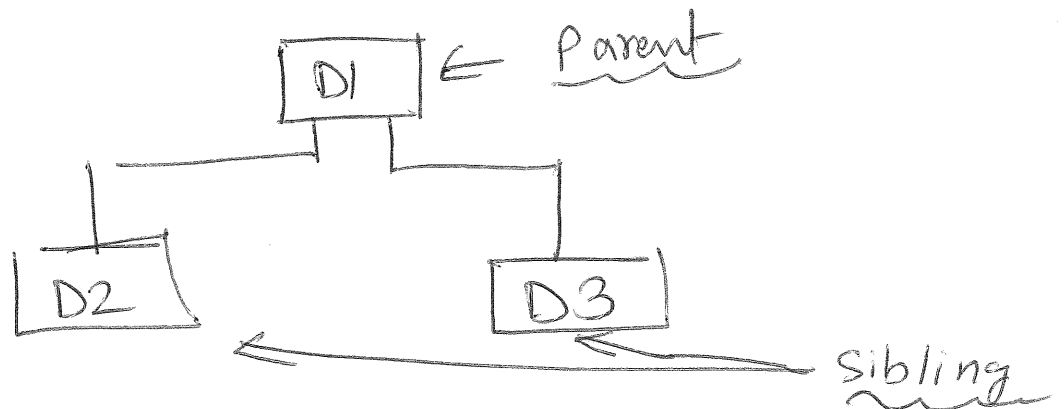

Navigating directories

cd / \leftarrow change directory to root directory

cd .. \leftarrow changes to parent directory

cd ../directoryname \leftarrow changes to sibling directory

$\left\{ \begin{array}{l} \bullet \leftarrow \text{current directory} \\ \bullet\bullet \leftarrow \text{parent directory} \\ \sim \leftarrow \text{HOME directory} \end{array} \right\}$

cd ../../ \leftarrow two levels up

IV

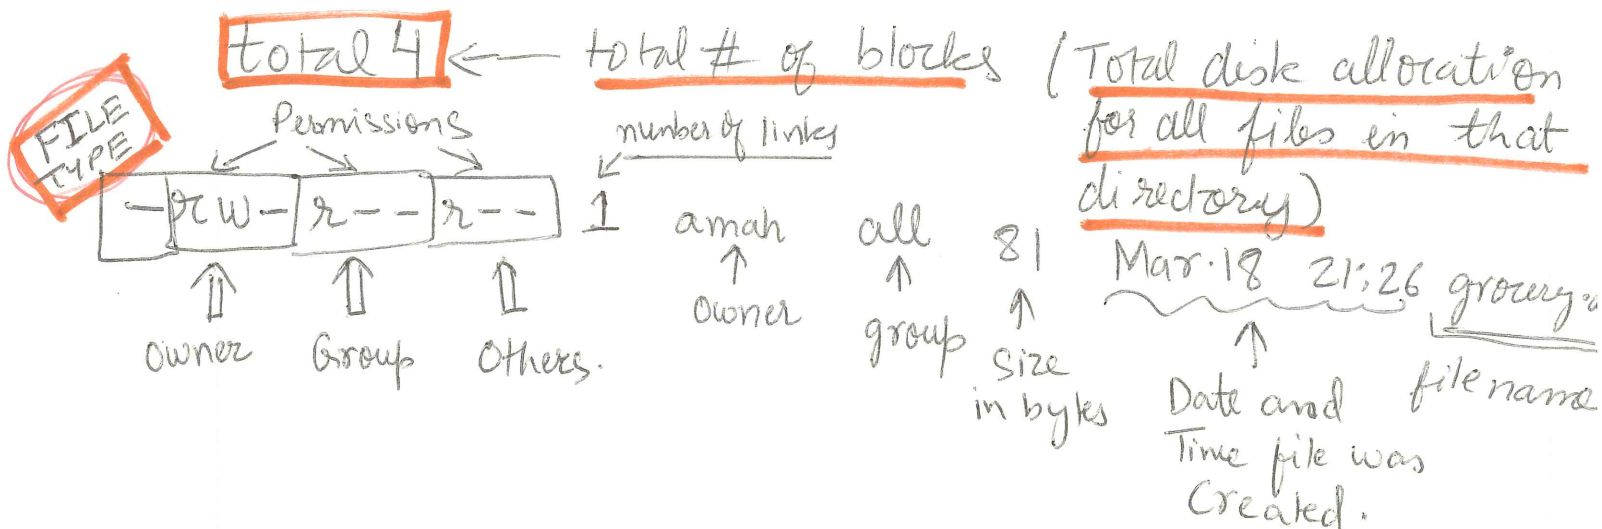

File Protection System

- ↔ Each user belongs to at least one group.
- ↔ Groups of a user are determined by the system administrator.

Super user → have access to any file and directory in the system.

ls -l in unix home

Three permissions

r : Read

w : Write and delete, rename

x : Execute

- : No permission

Difference between Read and Execute

- 1) Read happens in case of data files, which are opened by programs and parsed.
 - 2) Execute happens when files are opened or run by the OS for the CPU. They contain instructions.
-

Change file permissions

r → 4	}	rwx → 7
w → 2		r-x → 5
x → 1		r-- → 4

u ← user
g ← group
o ← others
a ← all three

chmod 744 filename.

chmod a-rwx filename

⊕ ← add permission

⊖ ← remove permission

VI

Unix looks at everything as a file

* File Types

- A normal file

d Directory

S- socket (network connection)

b Block device sends data in blocks
(e.g. HD, USB drive)

c Character device sends single characters
(e.g. serial ports, sound cards)

Permissions

r Read

w Write

~~x~~ Execute ← For directories, means you can do a directory listing for sub directories.

- No access

Link counts

1 ← file

2 ← Directory

} starting.

ls -a ← Shows hidden files

mkdir ← creates a directory

rmdir ← deletes an empty directory

File Management Commands

COPY { cp ← create copy of original
cp [option] source destination
-i ← interactive mode

MOVE { mv ← move command
mv source destination
← Renames in same directory

Source and destination can have same name only when moving file to another directory

REMOVE { rm filenames ← deletes files permanently
rm -i ← interactive mode
rm -f ← delete forcibly
rm -rf to recursively delete files in a directory without prompting
